# Primitive Polynomials (Mod 2) 

By E. J. Watson

The following list contains one example of a primitive polynomial (mod 2) for each degree $n, 1 \leqq n \leqq 100$. It was compiled with the aid of the Mercury computer at Manchester University by the following method.

The polynomials $P_{n}(x)(\bmod 2)$ of degree $n$ were tested in their natural order until a primitive polynomial was found. The test comprised three stages. In the first stage the small primes, of degree up to 9 , were tried as possible factors (mod 2) of $P_{n}$. If no factor was found $P_{n}$ went forward to the second stage, which tested whether $P_{n}$ divides $x^{N}-1$, where $N=2^{n}-1$. If it does, and $N$ is prime (a Mersenne prime), this suffices to prove that $P_{n}$ is primitive. If $N$ is composite, however, $P_{n}$ might divide $x^{M}-1$, where $M$ is a factor of $N$, and then $P_{n}$ would not be primitive. The third stage was, therefore, a trial of this possibility, in which $M$ took the values $N / p$, where $p$ runs through the prime factors of $N$.

The two latter stages were carried out by a process in which the computer repeated the operations of squaring, possibly multiplying by $x$ (depending on the binary representation of $M$ ), then dividing by $P_{n}$. The prime factors of $N$ were taken from the tables of Kraïtchik [1], supplemented by Robinson's [2] further decomposition of $2^{95}-1$. If any more of these 'prime' factors should turn out to be composite, doubt would be cast on the corresponding $P_{n}$. Mersenne polynomials for $n=107$ and 127 are also given. The prime $x^{127}+x+1$ was found by Zierler [3]. Its nature follows from the general result that if $\Sigma a_{n} x^{n}$ divides $\Sigma c_{n} x^{n}(\bmod p)$, then

$$
\Sigma a_{n} x^{p^{n}} \quad \text { divides } \quad \Sigma c_{n} x^{p^{n}} \quad(\bmod p) .
$$

The primitive character of each polynomial $P_{n}(x)$ listed has been checked by a repetition of the second and third stages on the conjugate polynomial $x^{n} P_{n}\left(x^{-1}\right)$. In the list only the degrees of the separate terms in $P_{n}$ are given, thus

$$
127 \quad 1 \quad 0 \quad \text { stands for } \quad x^{127}+x+1
$$
